2.2 Overview of product content	4

# 1 Introduction

In order to exploit the the MET Norway Scientific Information System (METSIS), the NBS has decided to make certain types of Sentinel satellite products available in NetCDF<sup>1</sup> format following the Climate and Forecast<sup>2</sup> (CF) convention, in addition to the original SAFE<sup>3</sup> format. The background is benchmarked in support for an open data space allowing combination with other types of data sets like model data & in-situ observations, support for spatio-temporal subsetting and product aggregation and integration of services, among others. In this document, the structure of the Sentinel-2 Level 1C (L1C) products is described.

The Sentinel-2 satellites carries a MultiSpectral Instrument (MSI). The MSI samples 13 spectral bands from the Visible (VNIR) and Near Infra-Red (NIR) to the Short Wave Infra-Red (SWIR) in three categories of spatial resoultions: four bands at 10 metres, six bands at 20 metres and three bands at 60 metres. Read more about the specifications of the Sentinel-2 mission at [sentinel.esa.int](https://sentinel.esa.int).

## 1.1 Scope

The scope of this document is to document the structure, content and outline of the NetCDF versions of the Sentinel-2 L1C products for the users.

## 1.2 Intended audience

The intended audience are the users of the NetCDF versions of the Sentinel-2 L1C products.

# 2 Product structure

The product file naming convention follows the same standard as the original top-level SAFE<sup>4</sup> products folder name in addition to the raster band variable names. However, the product variables are not all equal. In the NetCDF products, all spectral bands are provided in the highest raster resolution i.e. 10m x 10m. For the spectral bands with lower original raster resolution, resampling has been applied using a nearest neighbor interpolation method preserving information when resampling to native resolution. In addition, view, sun and zenith angles are resampled to highest raster resolution (originally 500m x 500m) and all band masks originally provided in GML that contains information are rasterized like clouds, detector\_footprint, nodata etc. Moreover, the .xml annotation files in SAFE are processed as character variables in NetCDF and can be printed/read as text string information.

## 2.1 Variable types

The datatypes used in these NetCDF files are described in the following table:

Variable type	Type description
byte	8 bit integer
ubyte	8 bit unsigned integer
short	16 bit integer
ushort	16 bit unsigned integer
int	32 bit integer
float	32 bit floating point
char	8 bit character

Table 1: Data types in NetCDF with description. The variable attribute `_Unsigned = "true"` indicates that the unsigned version of the variable is used. E.g `ubyte` is in the range [0,255].

Each variable contains attributes describing the data. For instance, each spectral band have `units = "1"` according to the CF standard names<sup>5</sup> table for `toa_bidirectional_reflectance`. For the spectral bands, we have also added the irradiance unit as `solar_irradiance_unit = "W/m2/um"`. See an example below in section 3.2.

## 2.2 Overview of product content

Below is an overview of the content of a random Sentinel-2 L1C product. The format of the output is similar to what you obtain from a `ncdump -h` command.

### Product: S2B\_MSIL1C\_\*
